

How Does the Web Work?

Web Browsers

Currently the most common browsers are Google Chrome, Safari, Microsoft Edge (replaced Internet Explorer), Firefox, and Opera. There are more out there, but these are the biggest.

We've seen that HTML (*Hypertext Markup Language*) files (webpages) are just text files with HTML code in them. The browsers job is to interpret the HTML code and then display the page.

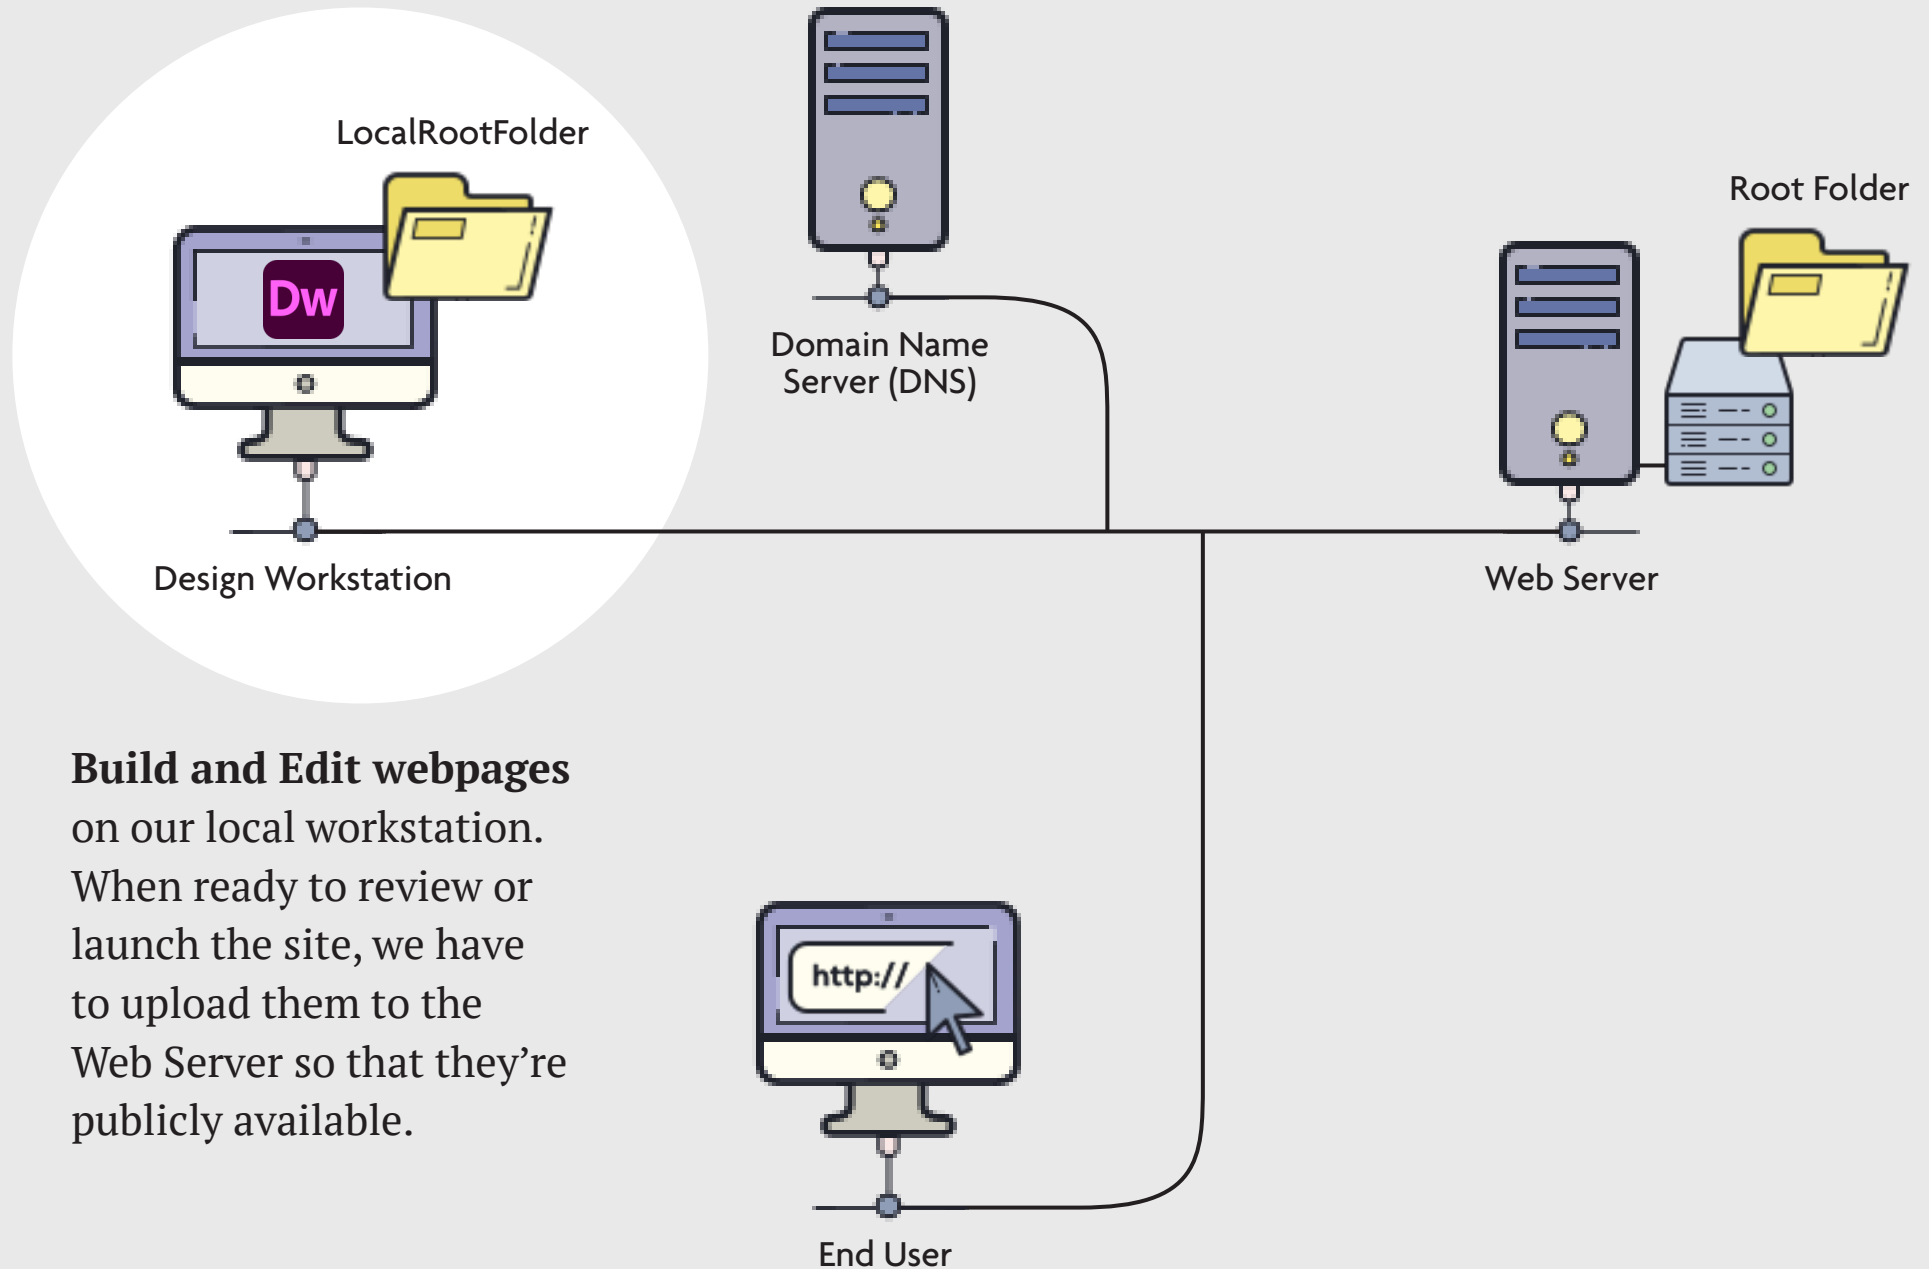

Screen Readers are used by sight impaired people. They scan the HTML code and read aloud the appropriate portions of the web code to the user.

Traffic on the Web

Build and Edit webpages on our local workstation. When ready to review or launch the site, we have to upload them to the Web Server so that they're publicly available.

Traffic on the Web

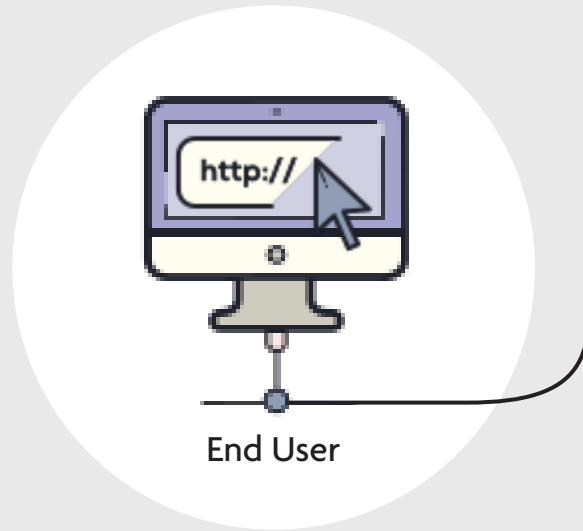

The **Web Server** is a computer on the internet renting web hosting, space for companies or individuals to save their website and make available to the public.

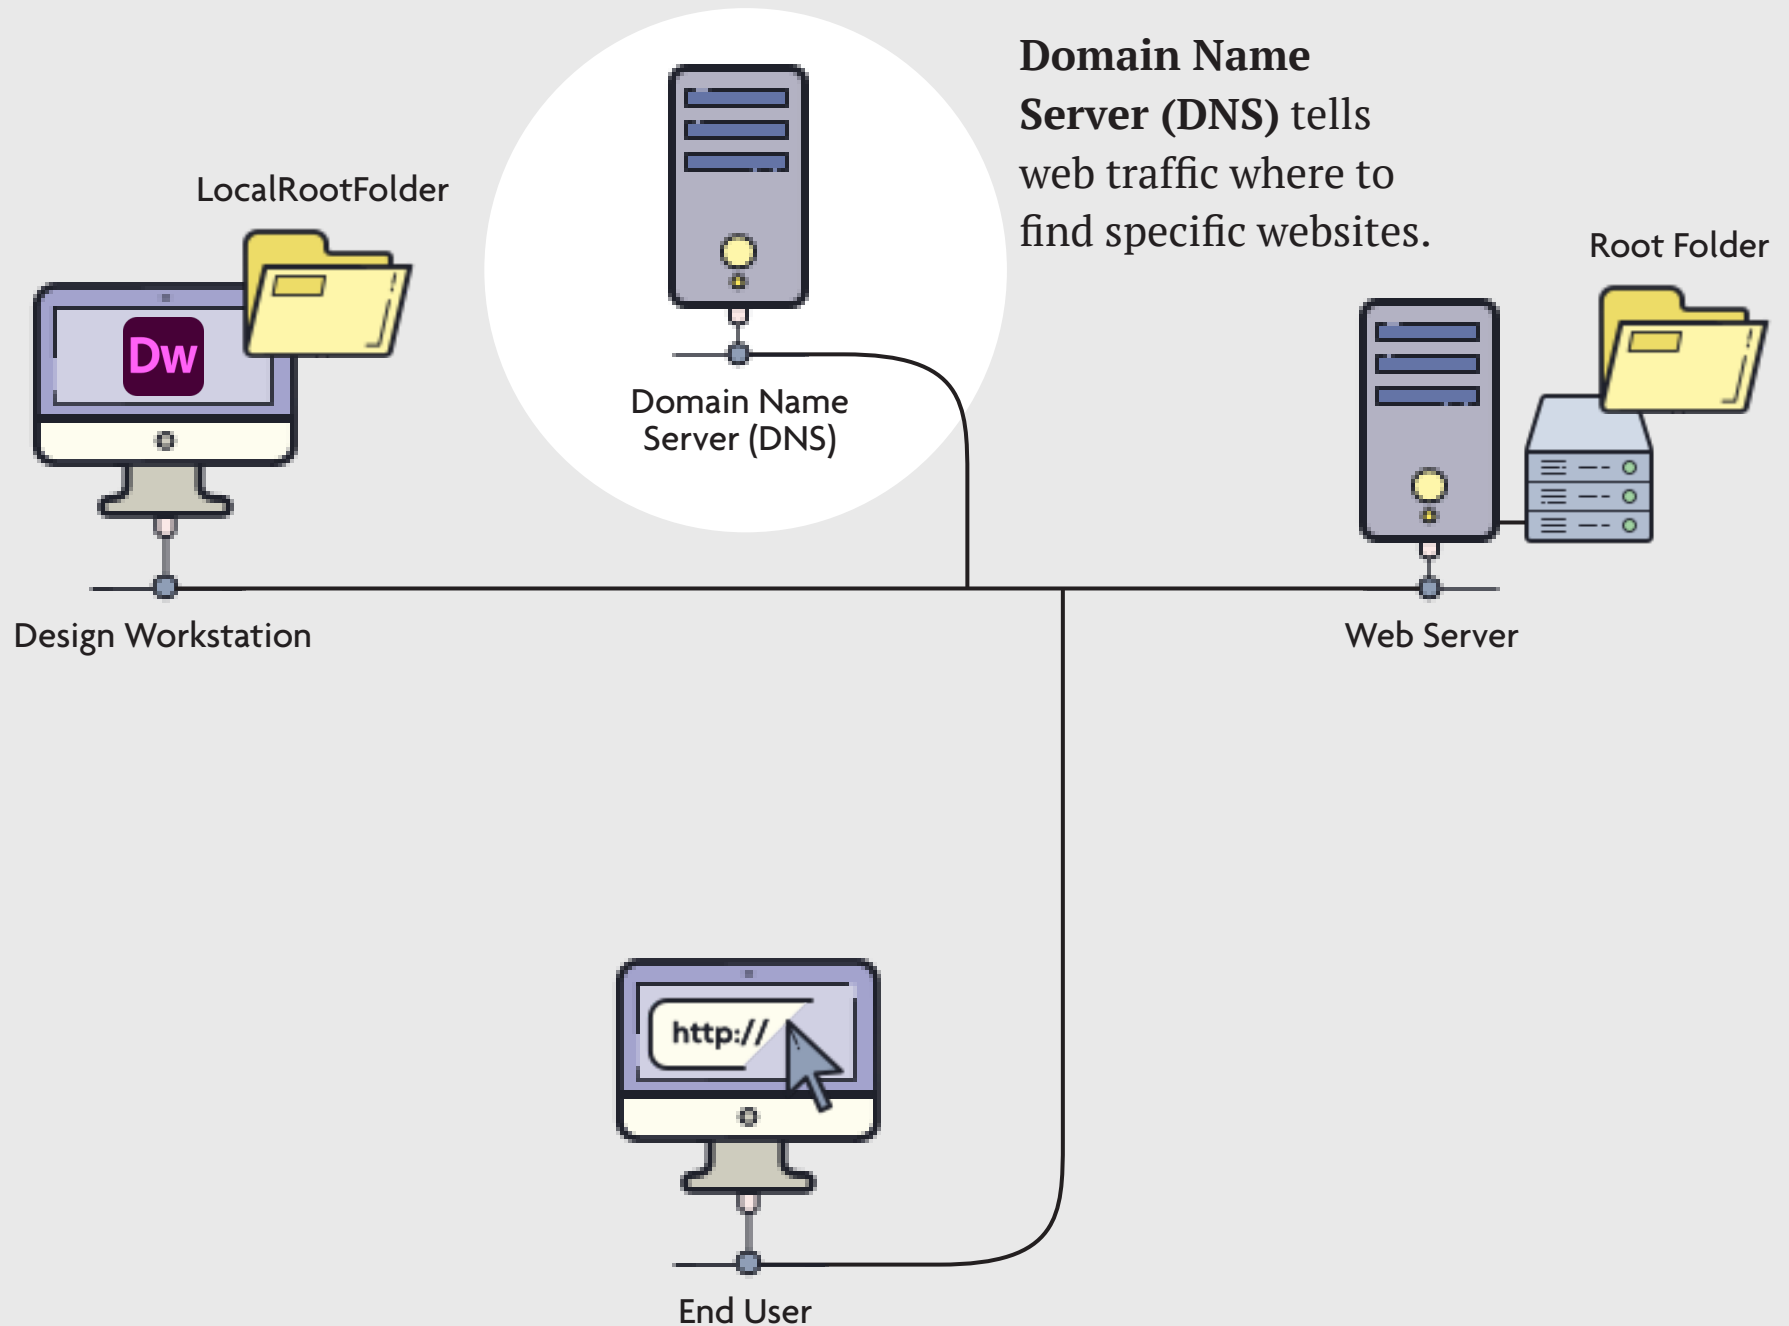

Traffic on the Web

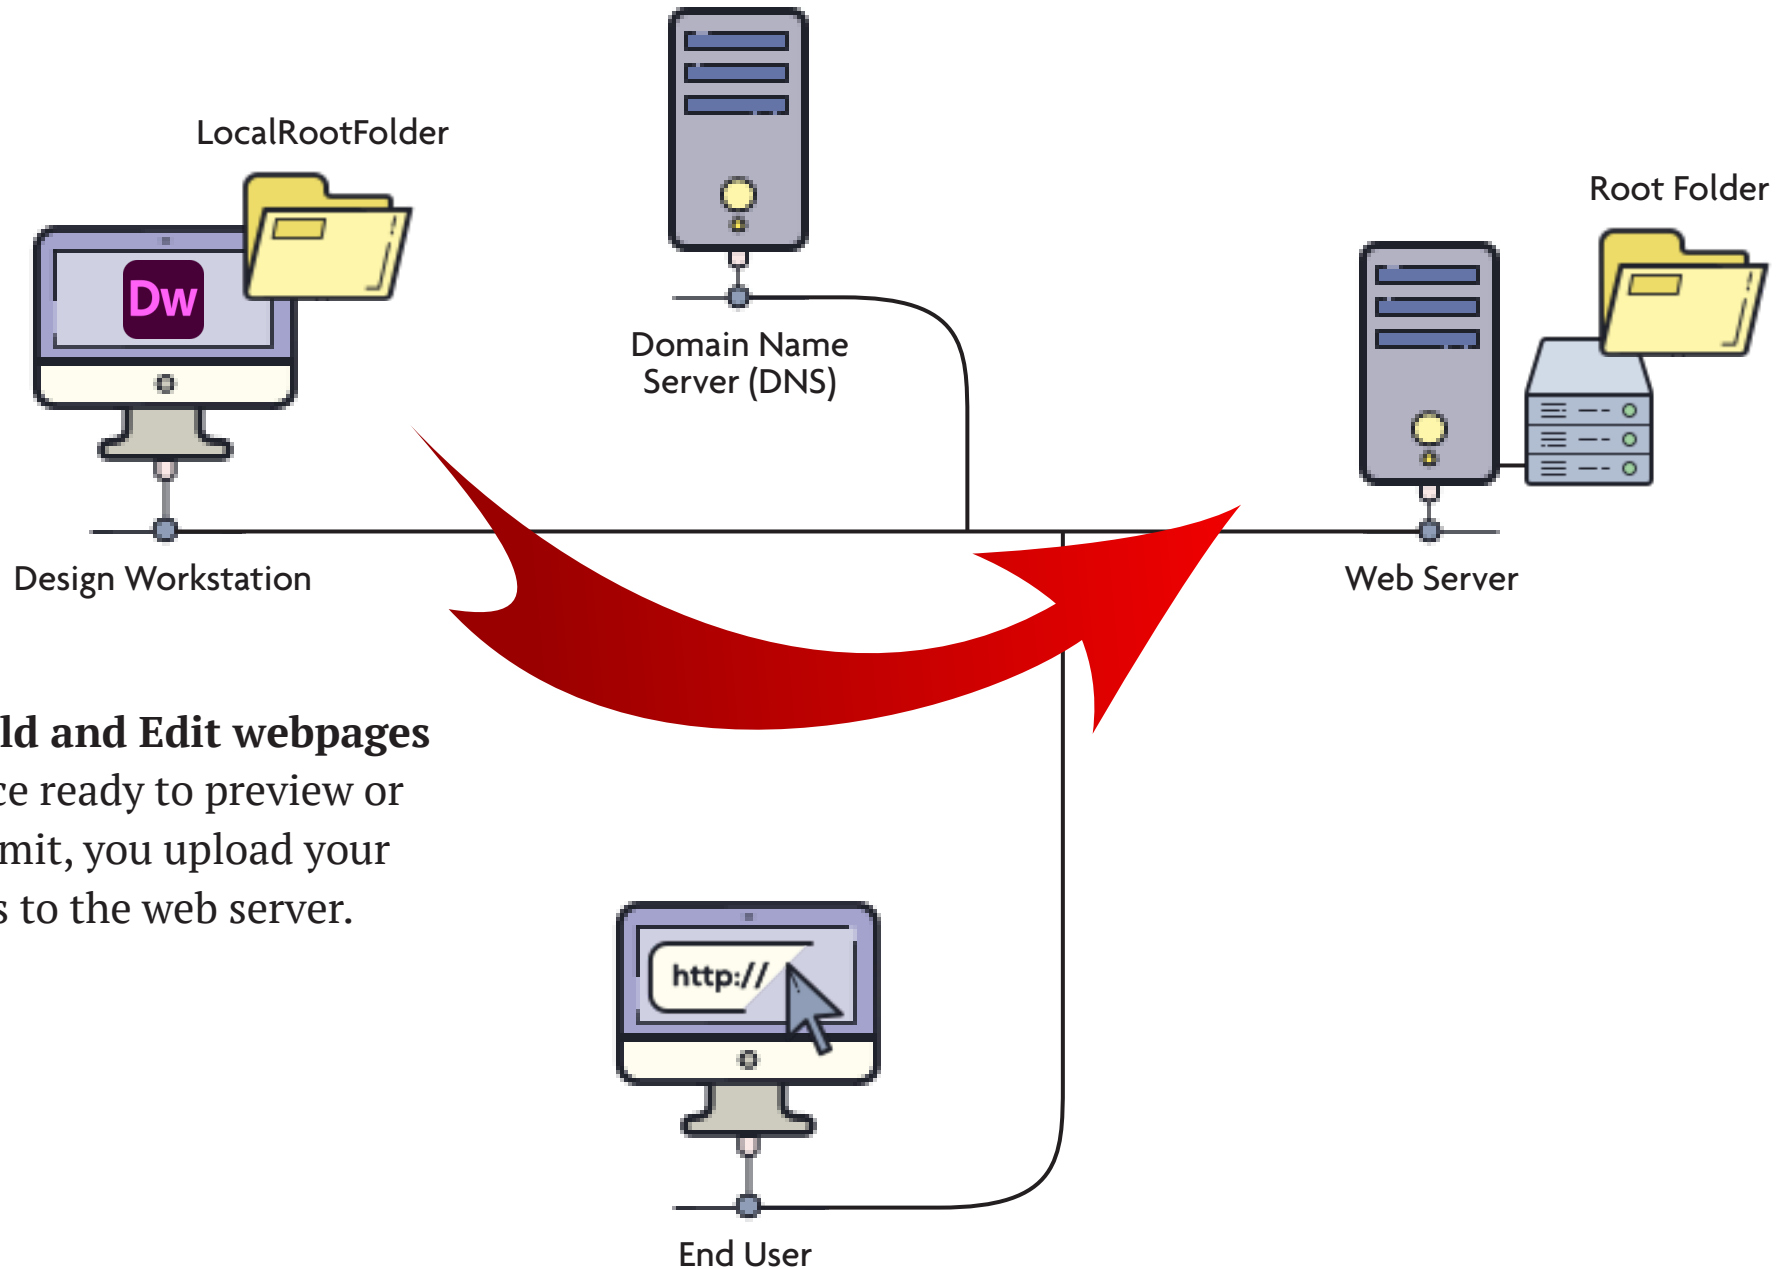

The end user accesses websites through a computer, tablet, or phone.

Traffic on the Web

Build and Edit webpages

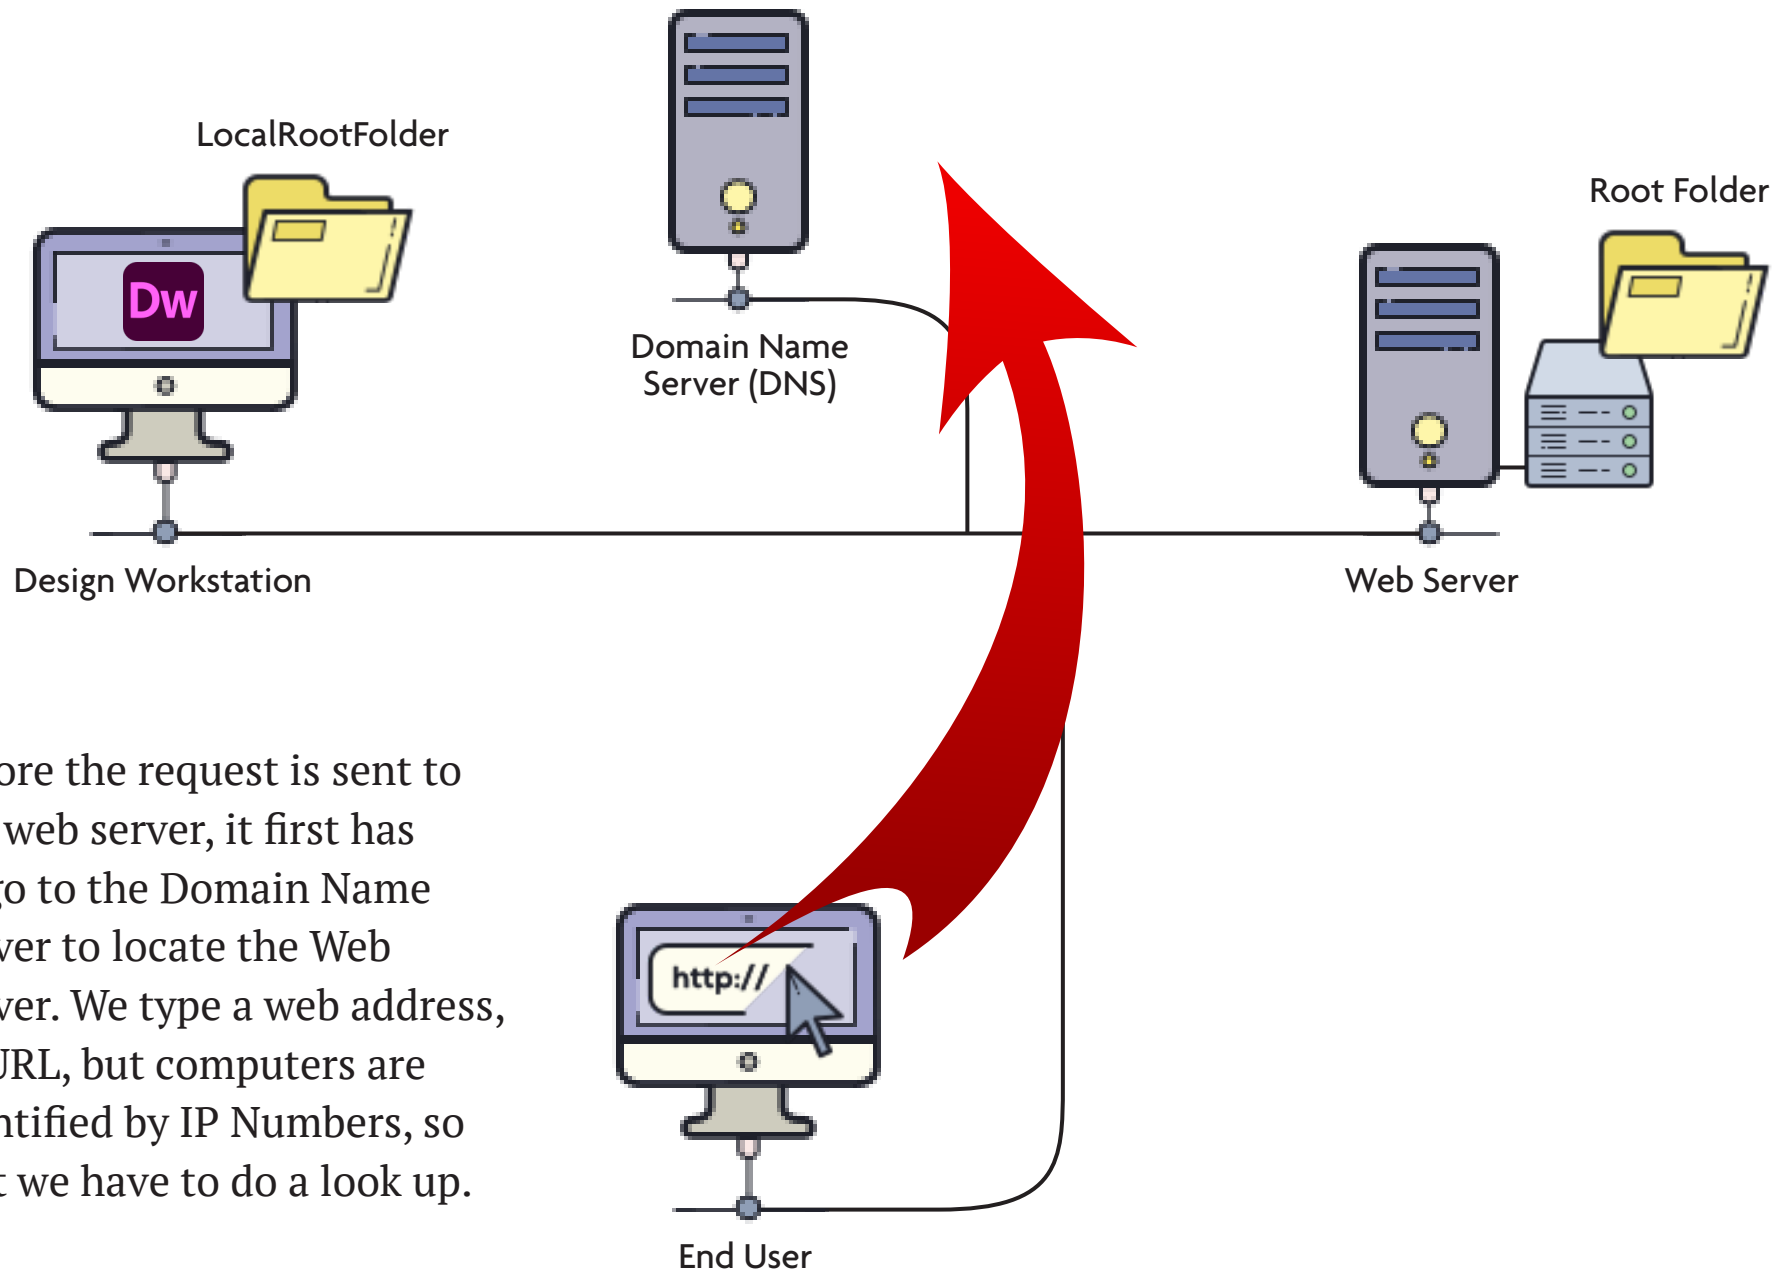

Once ready to preview or submit, you upload your files to the web server.

Traffic on the Web

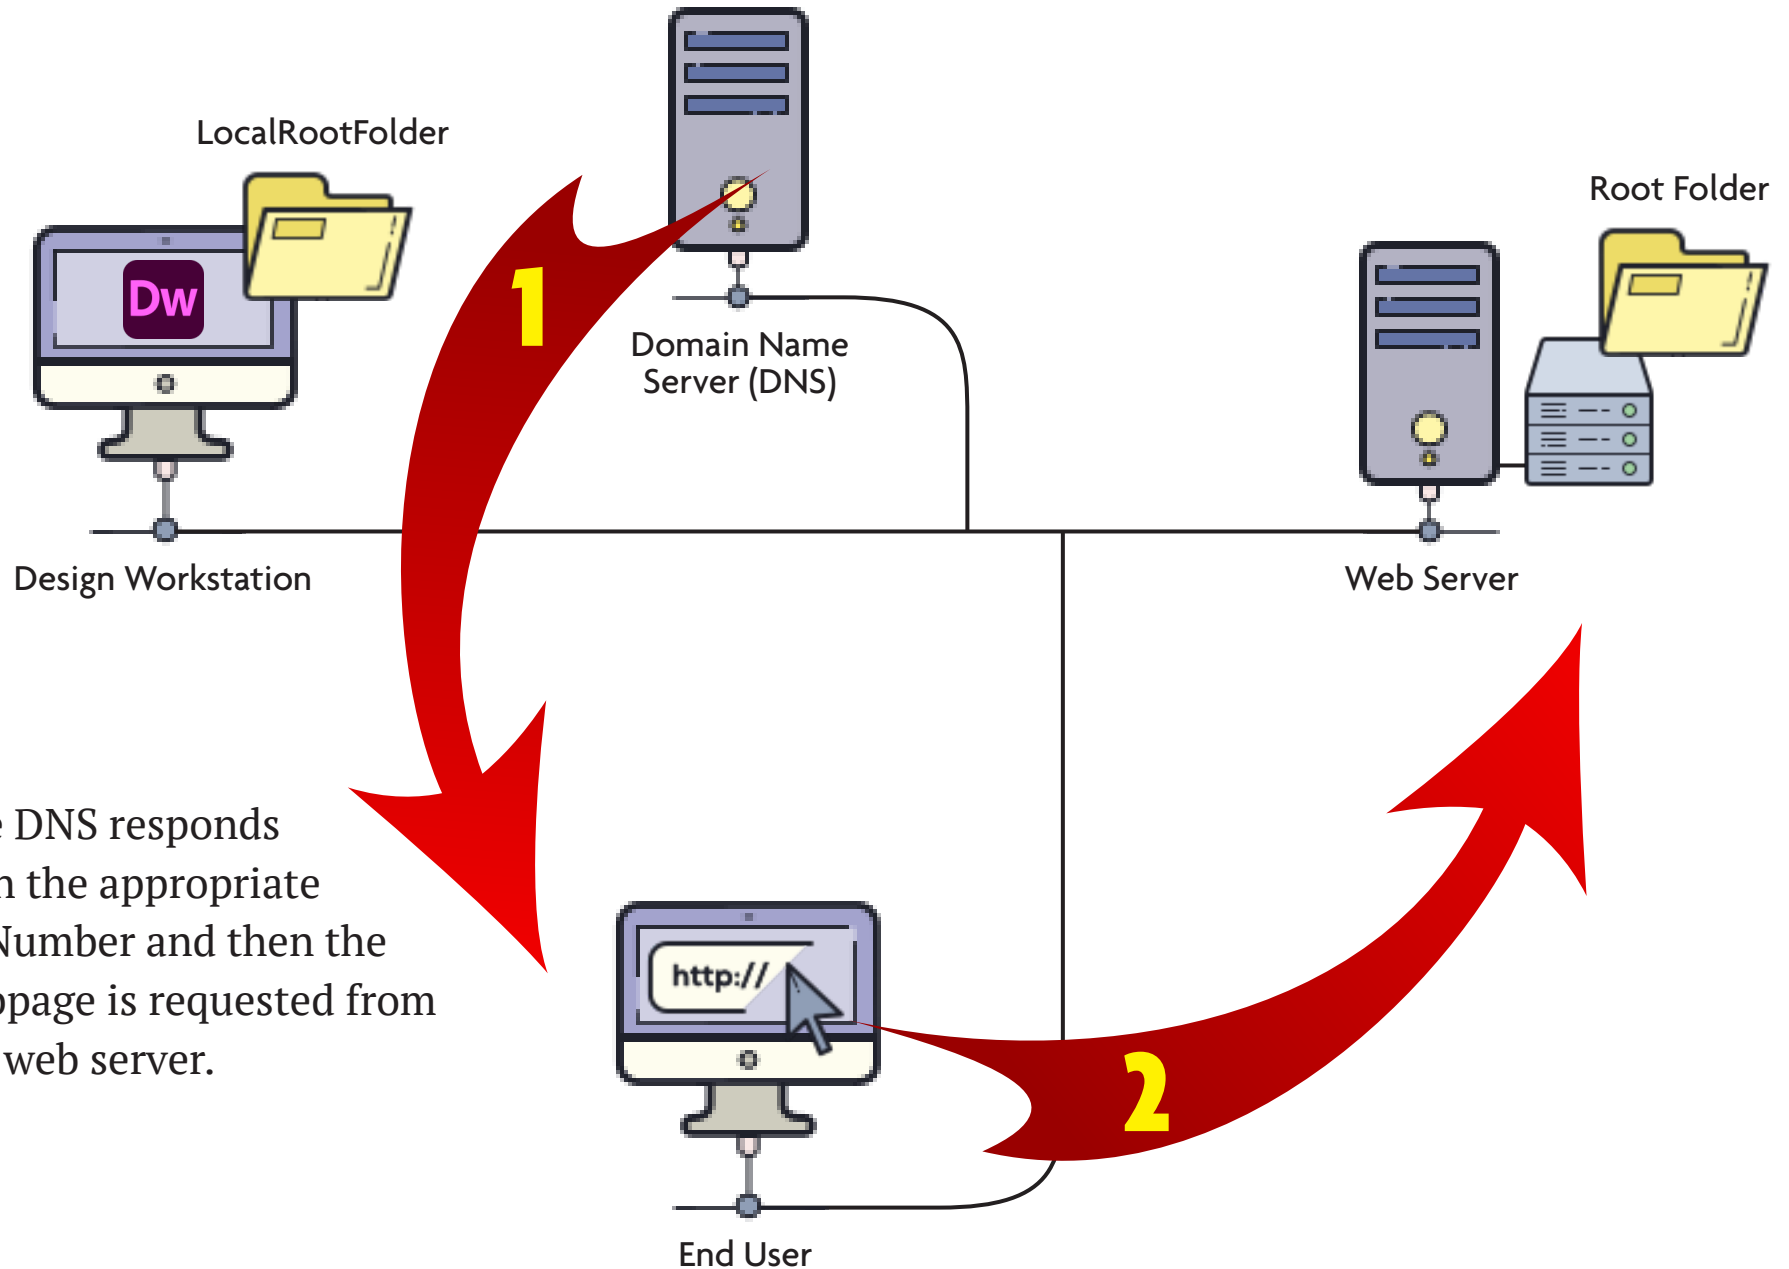

To **view webpages** a request has to be sent to the web server for the files (web pages are just text files containing HTML code).

Traffic on the Web

Before the request is sent to the web server, it first has to go to the Domain Name Server to locate the Web Server. We type a web address, or URL, but computers are identified by IP Numbers, so first we have to do a look up.

Traffic on the Web

The DNS responds with the appropriate IP Number and then the webpage is requested from the web server.
